PuMaS for Multiple Response Pk/Pd

Chris Rackauckas

22nd October 2018

1 Introduction

This is an introduction to PuMaS, a software for pharmacometric modeling and simulation. In this tutorial we will show how to simulate from a multiple response PK/PD model defined by ordinary differential equations, and how to extract information about the solution.

1.1 Installation

Because PuMaS is still unregistered, you will need to give the Git repository in order to add the package. To do this, use the command <code>ladd https://github.com/UMCTM/PuMaS.jl</code>. Doing it this way, PuMaS and its dependencies will install automatically. If one cannot authenticate for this command (since the repository is currently private!), then first clone the repository how you please, use <code>ldev path/to/package</code>, then then do <code>lbuild PuMaS</code>. Using the build command will download and install the dependencies.

1.2 Getting Started

To load the package, use using PuMaS

1.3 Our Example Model

1.4 Using the @model Macro

Now let's define a model. A model is defined in an Qmodel block. Inside of this block we have a few subsections. The first of which is Qparam. In here we define what kind of parameters we have. For this model we will define a vector parameter θ of size 12:

```
\begin{array}{l} {\tt Oparam \ begin} \\ \theta \in {\tt VectorDomain(12)} \\ {\tt end} \end{array}
```

Next we define our random effects. The random effects are defined by a distribution from Distributions.jl. For more information on defining distributions, please see the Distributions.jl

documentation. For this tutorial, we wish to have a multivariate normal of 11 uncorrelated random effects, so we utilize the syntax:

Notice that here we imported I from LinearAlgebra and and said that our Normal distribution's covariance is said I, the identity matrix.

Now we define our pre-processing step in **@pre**. This is where we choose how the parameters, random effects, and the covariates collate. We define the values and give them a name as follows:

```
Opre begin
                  = \theta[1]
     Ka1
     CL
                  = \theta[2] * \exp(\eta[1])
      Vс
                  = \theta[3] * \exp(\eta[2])
                  = \theta[4] * \exp(\eta[3])
      Vр
                 = \theta[5] * \exp(\eta[4])
                 = \theta[6] * \exp(\eta[5])
     Kin
     Kout
                 = \theta[7] * \exp(\eta[6])
      IC50
                  = \theta[8] * \exp(\eta[7])
      XAMI
                 = \theta[9] * \exp(\eta[8])
                  = \theta[10] * \exp(\eta[9])
                 = \theta[11] * \exp(\eta[10])
      Vmax
                  = \theta[12] * \exp(\eta[11])
end
```

Next we define the **@init** block which gives the inital values for our differential equations. Any variable not mentioned in this block is assumed to have a zero for its starting value. We wish to only set the starting value for **Resp**, and thus we use:

```
Cinit begin

Resp = \theta[6]/\theta[7]

end
```

Now we define our dynamics. We do this via the **@dynamics** block. Differential variables are declared by having a line defining their derivative. For our model, we use:

Lastly we utilize the **@derived** macro to define our post-processing. We can output values using the following:

```
\begin{array}{rcl} \textbf{@derived begin} \\ & \text{ev1} & = \text{Ev1} \\ & \text{cp} & = \text{Cent} \ / \ \theta \text{[3]} \\ & \text{periph} & = \text{Periph} \\ & \text{resp} & = \text{Resp} \\ & \text{end} \end{array}
```

The Qmodel block is all of these together, giving us the following model:

```
using LinearAlgebra
model = @model begin
     @param begin
       \theta \in \texttt{VectorDomain}(12)
     end
     @random begin
       \eta \sim MvNormal(Matrix{Float64}(I, 11, 11))
     Opre begin
          Ka1
                    = \theta[1]
          CL
                    = \theta[2]*exp(\eta[1])
                    = \theta[3] * \exp(\eta[2])
          Vс
          Q
                    = \theta[4] * \exp(\eta[3])
                   = \theta[5] * \exp(\eta[4])
          ďγ
                   = \theta[6] * \exp(\eta[5])
          Kin
          Kout
                   = \theta[7] * \exp(\eta[6])
          IC50
                   = \theta[8] * \exp(\eta[7])
                 = \theta[9] * \exp(\eta[8])
          IMAX
                   = \theta[10] * \exp(\eta[9])
                 = \theta[11] * \exp(\eta[10])
          Vmax
                   = \theta[12] * \exp(\eta[11])
     end
     @init begin
          Resp = \theta[6]/\theta[7]
     end
     @dynamics begin
          Ev1'
                    = -Ka1*Ev1
                   = Ka1*Ev1 - (CL+Vmax/(Km+(Cent/Vc))+Q)*(Cent/Vc) + Q*(Periph/Vp)
          Cent'
          Periph' = Q*(Cent/Vc) - Q*(Periph/Vp)
                  = Kin*(1-(IMAX*(Cent/Vc)^{\gamma}/(IC50^{\gamma}+(Cent/Vc)^{\gamma}))) - Kout*Resp
     end
     @derived begin
          ev1
                  = Ev1
                  = Cent / \theta[3]
          periph = Periph
          resp
                  = Resp
     end
end
```

1.5 Grabbing Data

In this tutorial we will utilize an example dataset in NMTRAN form. To bring in data we utilize the process_nmtran function. The first argument is the path to the dataset. The path to our example data is example_nmtran_data("event_data/data23"). Next we give it the name of the covariate from the dataset. Our example data has no covariates, so we note this as []. Lastly, we declare the names of the columns which correspond to the observation variables. In this dataset, we have observations for all of [:ev1,:cp,:periph,:resp]. Together, this gives us the command:

```
pop = process_nmtran(example_nmtran_data("event_data/data23"),[],
        [:ev1,:cp,:periph,:resp])
```

That gives us a whole population. If we wish to grab a subject out of the population, we simply index the population. Let's grab the first subject:

```
subject = pop[1]
```

1.6 Running a Simulation

The main function for running a simulation is simobs. simobs on a population simulates all of the population (in parallel), while simobs on a subject simulates just that subject. If we wish to change the parameters from the initialized values, then we pass them in. Let's simulate subject 1 with a set of chosen parameters:

```
x0 = (θ = [

1, # Ka1 Absorption rate constant 1 (1/time)
1, # CL Clearance (volume/time)
20, # Vc Central volume (volume)
2, # Q Inter-compartmental clearance (volume/time)
10, # Vp Peripheral volume of distribution (volume)
10, # Kin Response in rate constant (1/time)
2, # Kout Response out rate constant (1/time)
2, # IC50 Concentration for 50% of max inhibition (mass/volume)
1, # IMAX Maximum inhibition
1, # γ Emax model sigmoidicity
0, # Vmax Maximum reaction velocity (mass/time)
2 # Km Michaelis constant (mass/volume)
],)
```

sim = simobs(model, subject, x0)

Notice that in our model we said that there was a single parameter θ so our input parameter is a named tuple with just the name θ . When we only give the parameters, the random effects are automatically sampled from their distributions. If we wish to prescribe a value for the random effects, we pass initial values similarly:

```
y0 = (\eta = zeros(11),)
sim = simobs(model, subject, x0, y0)
```

The points which are saved automatically match the observations from the dataset. If you wish to change the saving time points, or did not have observations in your dataset, pass the keyword argument obstimes. For example, let's save at every 0.1 hours and run the simulation for 19 hours:

```
sim = simobs(model, subject, x0, y0, obstimes = 0:0.1:19)
```

1.7 Handling the SimulatedObservations

The resulting SimulatedObservations type has two fields. sim.times is an array of time points for which the data was saved. sim.derived is the result of the derived variables. From there, the derived variables are accessed by name. For example,

```
sim.derived.cp

191-element Array{Float64,1}:
    0.0
    0.47221914014817434
```

```
0.892563879689724
```

- 1.2661629995273587

From there, any Julia tools can be used to analyze these arrays and DataFrames. For example, if we wish the plot the result of ev1 over time, we'd use the following:

using Plots
plot(sim.times,sim.derived.ev1)
